

Last session drop: Content that we covered that you might not have documented or ability to recall.

1. You were beginning to plan coding to make postal mail communications functional and looking at the code. I believe that you looked at several requests and saw no home address and you seemed to be the code wasn't built. I entered a test request and realized that at some point the chat no longer asked for home address.

2. At that point I derailed your effort and mentioned an idea somewhat related that would capture address, make it easier for the user, reduce number of volleys in the request chat and eliminate some complexity in the script as well as what was a clumsy and confusing presentation of text boxes in the chat. The idea: Move the chat window far to the right. In the open space between left side of the chat agent box and left edge, have a box that allows a requestor to simply type the information in without using the chat agent, and when finished, click "Proceed to AI Search" button. We decided to design the box so that it forces the requestor to either verify email address or click to acknowledge that he had visually reviewed the email address for accuracy. The box would be look "live" at the top where the Name and email address entered down to the buttons for Send Email Verification and Verification Email Recieved, as well as the button for click to indicate the the email address has been visually checked for accuracy. Below that, the screen is dimmed and the requestor cant access the text boxes until either Verification Email Recieved or Visually Reviewed for Accuracy button is pushed. The requestor completes filling out the information, clicks to proceed and that triggers the chat agent to turn on. Tentatively, the script would be "Thank you for using the {city name} AI Powered Open Record Search. I will work with you to create description content that assures optimal search results. It is important to note that if you are requesting more than one type of record, it is important that the search description for each is entered invidually. Please enter a description of a requested record" That chat agent asks questions to clarify or request additional information until the user has no more information to provide or stops before that point if the description seems to be complete and properly worded. The agent then says "Your request is as follows: (types final content), do you agree?" If yes, the request is submitted. This is where I should mention the results window. After the requestor enters information in the box on the left and clicks proceed, is dissolves, and a large box that fills the entire area slides in. At the top is a thin section with instructions. On he right is a vertical box that will hold selected records, maybe 25 percent of the width of the entire window (and selected items showing much smaller fonts than results. The agent says "Review Search results. Selected records will move to the panel on the right. Instructions on screen say when selection is completed or when you determine that no records match, click "Proceed" button at the bottom. The sceen fades to dark and the results still showig in the window disappear. A multi select with click button is at the bottom of the right column. Two Options to select from. First is "Download all public ready records indetified by the green tag, then submit remaining records for required processing" Second is Submit all records for required processing. At that point the agent says "would you like to search for more records?" if yes, loop back to Please enter a description of a requested record"...continue until the answer to the question is No. In the loop the agent is aware of whether a specific description is for email or for police video. In bogth cases the agent mentions that the request is for a type of record than can not be included immediately in results and the search will be conducted by the Open Records team.

That is where the session crashed.
